Swaption As a Missing Link in Asset Allocation

Swaption As a Missing Link in Asset Allocation

Global Financial Crisis

High inflation period

Mathematics of Pricing Swaptions

A swaption is a financial derivative that can be described as an option to exchange a fixed rate bond for floating rate bonds for a predetermined principal. There are two types of swaptions, payer swaptions and receiver swaptions. A payer swaption gives the holder the right to pay a fixed interest rate and receive a floating rate, similar to a call option in the stock market. On the other hand, a receiver swaption allows the holder to pay a floating interest rate and receive a fixed rate, resembling a put option.

One-Factor Short-Rate Model

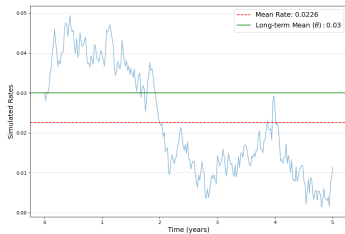

The Vasicek model

$$dr_t = \kappa [\theta - r(t)] dt + \sigma dW(t) \quad (1)$$

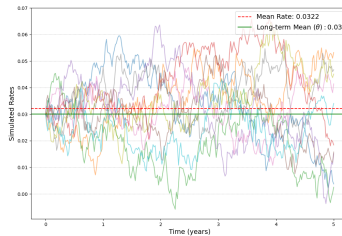

$$r(0) = r_0 \quad (2)$$

The parameters in the short rate dynamic κ , θ and σ are positive constants. Where κ represent the mean reversion speed, θ is the long-term average rate, σ is the volatility and $W(t)$ is a Wiener process.

One-Factor Short-Rate Model

Constant Volatility

The SABR Model

The SABR model consists of a dynamic for the forward price and one for the volatility, since the SABR model is a two-factor model. The SABR model also formulates how the two processes are correlated.

$$d\hat{F}_t = \hat{\alpha}_t \hat{F}_t^\beta dW_t^1, \quad \hat{F}(0) = f \quad (3)$$

$$d\hat{\alpha}_t = \nu \hat{\alpha}_t dW_t^2, \quad \hat{\alpha}(0) = \alpha \quad (4)$$

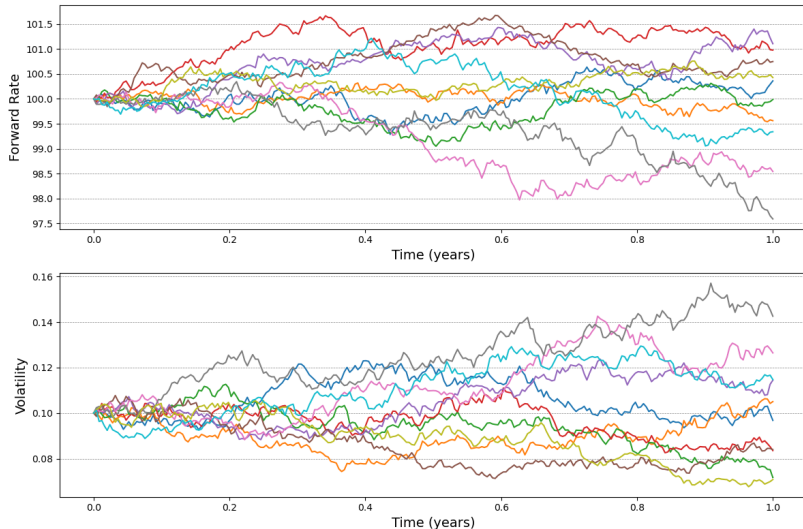

where W_t^1 and W_t^2 are correlated Wiener process and it is assumed that.

$$dW_t^1 dW_t^2 = \rho dt \quad (5)$$

The SABR Model

- F_0 — Initial forward rate or asset price.
- α_0 — Initial volatility.
- β — Elasticity parameter.
- ν — Volatility of the volatility parameter.
- ρ — Correlation between the asset price and its volatility.

The SABR Model

Ten simulated paths for the forward rate and the volatility in the SABR model.

The SABR Model

The paper Managing Smile Risk of Hagen (2002) states that under the SABR model, the prices of European options is given by Black formula

$$V_{\text{call}} = D(t_{\text{set}})fN(d_1) - KN(d_2) \quad (6)$$

$$V_{\text{put}} = V_{\text{call}} + D(t_{\text{set}})[K - f] \quad (7)$$

with

$$d_{1,2} = \frac{\log \frac{f}{K} \pm \frac{1}{2}\sigma_B^2 t_{\text{ex}}}{\sigma_B \sqrt{t_{\text{ex}}}} \quad (8)$$

here t_{set} is the settlement date and t_{ex} os the exercise date

The SABR Model

The implied volatility $\sigma_B(f, K)$ is given by

$$\sigma_B(K, f) = \frac{\alpha}{(fK)^{(1-\beta)/2}} \left\{ 1 + \frac{(1-\beta)^2}{24} \log^2 \frac{f}{K} + \frac{(1-\beta)^4}{1920} \log^4 \frac{f}{K} + \dots \right\} \left(\frac{z}{x(z)} \right). \quad (9)$$

where

$$z = \frac{\nu}{\alpha} (fK)^{(1-\beta)/2} \log \frac{f}{K}, \quad (10)$$

$$(11)$$

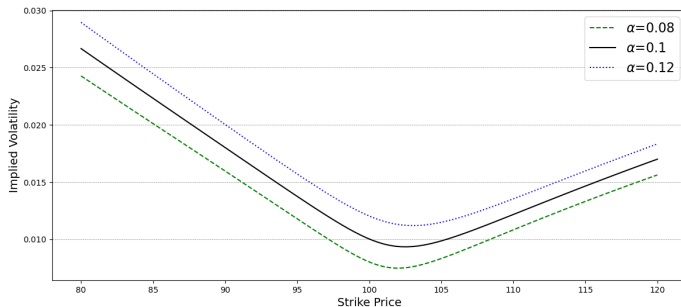

and $x(z)$ is defined by

$$x(z) = \log \left\{ \frac{\sqrt{1 - 2\rho z + z^2} + z - \rho}{1 - \rho} \right\}. \quad (12)$$

For the special case of at-the-money (ATM) options, options strike at $K = f$, this formula reduces to

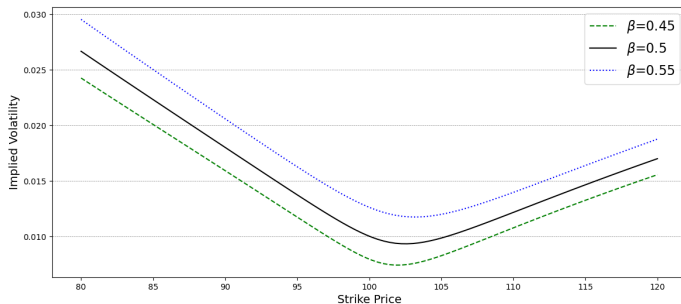

$$\sigma_{ATM} = \sigma_B(f, f) = \frac{\alpha}{f^{1-\beta}} \left\{ 1 + \left(\frac{(1-\beta)^2}{24} \frac{\alpha^2}{f^{2-2\beta}} + \frac{\rho\beta\nu}{4} \frac{\alpha}{f^{1-\beta}} + \frac{2-3\rho^2}{24} \nu^2 \right) t_{\text{ex}} + \dots \right\}. \quad (13)$$

The SABR Model

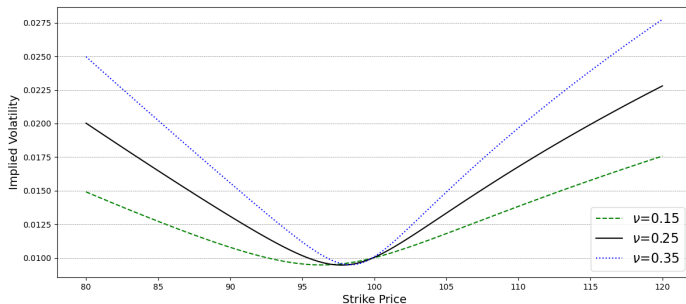

SABR model volatility smiles at various α_0 levels

The SABR Model

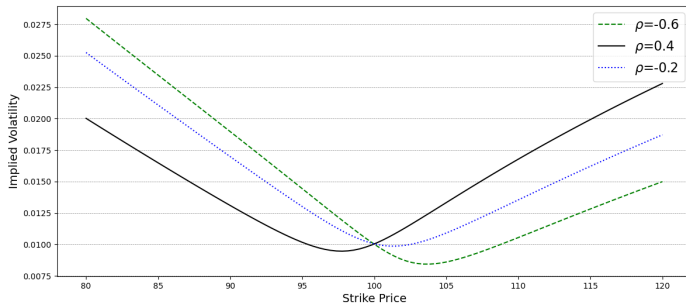

SABR model volatility smiles at various β levels

The SABR Model

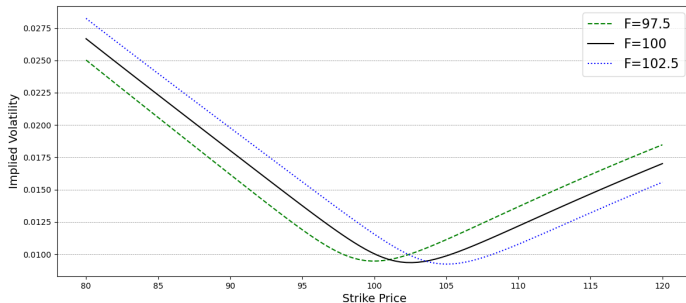

SABR model volatility smiles at various ν levels

The SABR Model

SABR model volatility smiles at various ρ levels

The SABR Model

SABR model volatility smiles at various F levels

Risk Related to The SABR Model

Changes in α parameter:

- Affects the level of the implied volatility smile.
- Higher α values increase the overall level of implied volatility.
- Lower α values decrease the overall level of implied volatility.

Fixing β parameter:

- Common practice since similar movements occur when changing both β and ν parameters.

Effect of β on the implied volatility smile:

- Lower β values make the smile steeper (more skewed).
- Higher β values flatten the smile.

Risk Related to The SABR Model

Effect of ν parameter:

- Higher ν values increase the curvature of the smile, making it more pronounced.
- Lower ν values decrease the curvature of the smile.

Effect of ρ parameter:

- Positive ρ values skew the smile to the right (towards higher strikes).
- Negative ρ values skew the smile to the left (towards lower strikes).

Effect of the forward price, f :

- Adjusts the center of the implied volatility smile.

Importance:

- Awareness of these movements in implied volatility is crucial if swaptions are included in asset allocation.

Conclusion

- Volatility is not constant.
- Model selection impacts swaption prices.
- Chose a two-factor model to handle stochastic volatility.
- Understanding risks of the SABR model is important.
- Swaption is a missing link i asset allocation.
